

ECC006 – Homework Assignment #7

Student: ABDULMUHSEN ALZOUBA | ID: 20215679

Question 1

How would you link to the named fragment **#jobs** on the page **employ.html** from the home page of the site?

✓ **Correct Answer: a) Jobs**

To link to a named fragment on another page, the href attribute must include both the filename and the fragment identifier separated by #. Option (b) uses the name attribute which is for defining anchors, not linking. Option (c) uses link which is not a valid anchor attribute. Option (d) would only work if you are already on employ.html.

Question 2

Which pseudo-element can be used to generate content that **precedes** an element?

✓ **Correct Answer: b) :before**

The :before (also written ::before) pseudo-element inserts generated content immediately before the content of the selected element. The :after pseudo-element inserts content after. :content and :first-line are not pseudo-elements used for content generation.

Question 3

Which of the following is a mobile web design best practice?

✓ **Correct Answer: c) Configure a single-column page layout.**

Mobile screens are narrow, so a single-column layout adapts best to small viewports without requiring horizontal scrolling. Multiple-column layouts are better suited for wide desktop screens. Lists are actually recommended for organizing information on mobile. Embedding text in images is discouraged because it cannot be resized or read by screen readers.

Question 4 – Find the Error

The page is intended to display the navigation area on the **right side** of the browser window. The error is in the CSS rule for the **nav** element:

```
nav { float: left; ... }
```

The **float: left** property causes the navigation to appear on the left. To move it to the right, it must be changed to **float: right**. Additionally, the padding in the main element should be

adjusted accordingly (e.g., padding: 20px 20px 20px 150px) so the main content does not overlap the navigation.

Fix:

```
nav { float: right; width: 120px; }
```

Web Research: Accessibility and Mobile Web Design

The W3C document *Web Content Accessibility and Mobile Web*

(<http://www.w3.org/WAI/mobile>) highlights a remarkable overlap between the practices that make websites accessible to people with disabilities and those that make websites work well on mobile devices. Both sets of guidelines share a common goal: ensuring that content is perceivable, operable, and understandable regardless of the device or ability of the user.

One of the most prominent shared areas is the use of **alternative text for images**. Screen readers used by visually impaired users rely on alt attributes to convey visual information, while mobile users on slow data connections benefit from meaningful alt text when images fail to load. Similarly, **proper use of headings** (h1–h6) creates a logical structure that benefits both screen reader navigation and mobile users who skim content on small screens.

Another shared practice is **avoiding reliance on a mouse or hover interactions**. Users with motor disabilities may navigate using keyboards or switch devices, while mobile users interact through touch — neither group uses a traditional mouse. Designing large, easily tappable targets directly addresses both needs. In addition, **avoiding fixed-size layouts** and preferring fluid or responsive designs supports screen magnification tools used by low-vision users and the varying screen widths of mobile devices.

Captions and transcripts for multimedia content serve both deaf users and mobile users in environments where audio is unavailable or distracting. Likewise, **minimizing the use of JavaScript** for critical functionality ensures that users with assistive technologies and users on older or limited mobile browsers can still access content.

In conclusion, web developers who follow WCAG (Web Content Accessibility Guidelines) will naturally produce sites that perform better on mobile devices, and vice versa. The most effective approach is to treat accessibility and mobile optimization not as separate concerns but as a unified design philosophy centered on universal usability. By adopting semantic HTML, responsive layouts, alternative text, and keyboard-friendly navigation from the start, developers can create websites that are inclusive, efficient, and future-proof.
